Abstract

Visual illusions are fascinating phenomena that have been used and studied by artists and 13 scientists for centuries, leading to important discoveries about the neurocognitive 14 underpinnings of perception, consciousness, and neuropsychiatric disorders such as 15 schizophrenia or autism. Surprisingly, despite their historical and theoretical importance 16 as psychological stimuli, there is no dedicated software, nor consistent approach, to 17 generate illusions in a systemic fashion. Instead, scientists have to craft them by hand in 18 an idiosyncratic fashion, or use pre-made images not tailored for the specific needs of their 19 studies. This, in turn, hinders the reproducibility of illusion-based research, narrowing possibilities for scientific breakthroughs and their applications. With the aim of addressing 21 this gap, *Pyllusion* is a Python-based open-source software (freely available at https://github.com/RealityBending/Pyllusion), that offers a framework to manipulate and generate illusions in a systematic way, compatible with different output formats such as 24 image files (.png, .jpg, .tiff, etc.) or experimental software (such as PsychoPy). 25 Keywords: Pyllusion, Visual Illusions, Optical Illusions, Schizophrenia, Python, 26 PsychoPy 27

A Parametric Framework to Generate Visual Illusions using Python

29

Visual illusions have been observed for hundreds of years (Luckiesh, 1965), many of which were described in print by Helmholtz (1856) in 1856 (Helmholtz, 1856). In general terms, 31 a visual illusion can be thought of as the inaccurate perception of a visual stimulus or a 32 given attribute, be it geometrical (size, shape, or angle), or another property such as colour 33 (Adelson, 2000; Delboeuf, 1893; Ebbinghaus, 1902; Howe & Purves, 2005; Muller-Lyer, 1896; Roberts, Harris, & Yates, 2005). Often, an illusory perception resists 'correction' in percep-35 tion even after an observer has been made aware of the misperception. Novel examples of illusions are still observed and have even cropped up on social media platforms, a famous example being 'The Dress Illusion' (as discussed by Schlaffke et al. (2015)), which some people perceive as white and yellow, whereas others as black and blue - this is thought to illustrate how perceptual priors (i.e., expectations regarding lighting conditions) can bias our conscious representation of an object. See Ninio (2014), Luckiesh (1965), and Robinson (1972) for extensive collections of visual illusions. Overall, these illusions show how our phenomenological experience is critically shaped by contextual information and prior expectations.

Entertainment value aside, illusions can serve a more practical utility. Visual illusions have helped scientists understand the architecture of the eye and its relationship with processes and structures involved further up stream in the brain, the dynamic interaction of these processes, and visual coding in the brain in general (Carbon, 2014; Clifford, 2002; Forte & Clifford, 2005). Illusions such as the blind-spot or those associated with colour perception, orientation perception, and motion perception, have all been informative of neuronal activity/processes both at the level of the eye and the brain via the measurement of associated illusions (Curran, Clifford, & Benton, 2009; Durgin, Tripathy, & Levi, 1995; Holland, 1965; MacKay, 1957; Webster, 1996; Witkin & Asch, 1948). Visual illusions, and perceptual illusions more generally, are a powerful tool in human perception and brain research,

which in turn can inform artificial cognitive systems design considerations (Boyce, Lindsay, Zgonnikov, Rano, & Wong-Lin, 2020; Carbon, 2014). Beyond low-level perceptual mechanisms, illusions can also be powerful tools to understand higher-order processes related to phenomenal consciousness (Mahon, Clarke, & Hunt, 2018), as well as neurocognitive disturbances.

The use of visual illusions to demonstrate contextual influences on visual perception (Chen, Chen, Gao, Yang, & Yan, 2015; Corbett & Enns, 2006; Roberts, Harris, & Yates, 2005) has 61 underlined their potential relevance in clinical contexts, for instance as markers or tools to investigate typical integration processes in schizophrenia (Clifford, 2014; Palmer, Caruana, Clifford, & Seymour, 2018; Thakkar et al., 2020). Indeed, several studies have demonstrated a diminished susceptibility to visual illusions amongst patients with schizophrenia 65 relative to healthy controls (King, Hodgekins, Chouinard, Chouinard, & Sperandio, 2017; Notredame, Pins, Deneve, & Jardri, 2014). People with schizotypal personality traits per-67 form significantly better at making accurate judgements of contrasts under contextual suppression (Dakin, Carlin, & Hemsley, 2005), are less prone to the perception of illusory motion (Crawford et al., 2010), and are less susceptible to visual size illusions (Uhlhaas, Silverstein, Phillips, & Lovell, 2004). While individuals along the schizophreniform spectrum display 71 apparent resistance to perceptual distortions, they concurrently experience a wide range of cognitive deficits [e.g., working memory, object naming, concentration; Liddle (1987)]. This 73 supports the idea that schizophrenia might be better characterized by a subset of specific processing abnormalities, rather than by a generalized neurocognitive impairment (Dakin, 75 Carlin, & Hemsley, 2005; Tibber et al., 2013). Specific perceptual anomalies in schizophrenia have also been highlighted using different classes of visual illusions that tap on distinct neurocognitive processes. For example, while patients with schizophrenia show a heightened resistance to contrast illusions, they are indistinguishable from healthy controls in judging brightness illusions (Tibber et al., 2013), arguing against a broad deficit in low-level perceptual integration since not all illusions are affected. In fact, other studies have emphasized the

role of high-level perceptual deficits in schizophrenia [e.g., problems in contextual processing
that manifest as greater resistance to the Ebbinghaus illusion; Massaro and Anderson (1971);
Uhlhaas, Phillips, Schenkel, and Silverstein (2006)]. However, the lack of consistency in the
tasks' methodologies has posed a significant challenge to advancing our theoretical understanding of the role of visual perception and reality construction in the psychopathology of
schizophrenia (King, Hodgekins, Chouinard, Chouinard, & Sperandio, 2017). Specifically,
the finding of an increased perceptual accuracy towards high-level illusions has failed to
replicate in several other studies (e.g., Parnas et al., 2001; Spencer & Ghorashi, 2014; Yang
et al., 2013), and other kinds of illusions (e.g., the Poggendorff illusion) have simply not been
sufficiently tested (Kantrowitz, Butler, Schecter, Silipo, & Javitt, 2009).

Individuals with autistic spectrum disorder (ASD) comprise another clinical group that demonstrates a similar immunity to perceptual biases, supporting the existence of diffi-93 culties in global processing and, conversely, an enhanced preference for idiosyncratic and detailed information (F. G. Happe, 1996). Hence, individuals with ASD appear as protected 95 as the clinical schizophrenia population against the contextual influences of illusions in biasing perception, allowing them to perceive elements accurately in a local fashion [referred to 97 as a 'weak central coherence'; Mitchell, Mottron, Soulieres, and Ropar (2010); Walter, Dassonville, and Bochsler (2009); Gori, Molteni, and Facoetti (2016)]. Some work has also been successful in delineating the underlying cognitive mechanisms employed by different illusions, 100 revealing that autistic traits in a typical population were related to greater resistance to the 101 Müller-Lyer illusion, but not the Ebbinghaus or Ponzo illusions (Chouinard, Noulty, Speran-102 dio, & Landry, 2013). One possible explanation for this dissociation relates to the extent of global processing engaged by the illusions, with the Müller-Lyer illusion (a within-object illusion where contextual elements and the target stimulus are physically joined) requiring 105 more cognitive resources for the local binding of features than the Ebbinghaus and Ponzo 106 illusions (a between-object illusion where contextual elements and the target stimulus are 107 physically separate) (Ben-Shalom & Ganel, 2012). Regardless, findings of illusion resistance 108

amongst ASD face similar low replicability rates as with the literature on schizophrenia,
even when the same illusion tasks are used (Hoy, Hatton, & Hare, 2004; Ropar & Mitchell,
11999). These mixed findings are attributed not only to the heterogenous nature of ASD
as a clinical population, but also to the large variability in experimental instructions (e.g.,
113 asking whether lines: "looked the same length"; vs. "were the same length," see F. Happe
114 and Frith (2006)) and the subsequent understanding of the task requirements (Chouinard,
115 Noulty, Sperandio, & Landry, 2013).

In summary, these studies suggest that illusions, rather than being mere perceptual artifacts, 116 engage specific neurocognitive processes involved in important higher order functions and 117 neuropsychiatric disorders. A common approach to explain illusory phenomena is using the 118 Predictive Coding framework (Friston & Kiebel, 2009), which posits that illusory perception 119 typically arises because of a strong systematic bias for prior beliefs (top-down influence) 120 that are mismatched with actual sensory evidence, causing the generation of an objectively 121 wrong but more plausible percept (i.e., two objectively equivalent-sized circles being inter-122 preted as different sizes because of their surrounding context) (Notredame, Pins, Deneve, & 123 Jardri, 2014). In the case of schizophrenia and also in other states of psychosis, a greater 124 resistance to visual illusions is then interpreted as a product of reduced adaptive top-down 125 influence (Koethe et al., 2009; Schneider et al., 2002) and an over-reliance on sensory evidence 126 (bottom-up processes) in making perceptual judgements (Dima, Dietrich, Dillo, & Emrich, 127 2010). While evidence from visual illusions research has garnered substantial support for the 128 predictive coding account, helping to underscore the neurocomputational mechanisms that 120 are fundamental to psychiatric and psychological disorders (Sterzer et al., 2018), there are 130 contradictory findings that fail to be integrated within this approach. The lack of consis-131 tency and replicability in experimental designs using illusion-based stimuli appear to be one 132 of the main hurdles precluding theoretical consensus in the field. 133

Despite the relevance of visual illusions in psychology and neuroscience, the field of illusion research lacks a dedicated software to generate and report the stimuli, in order for them to be

reproduced and re-used by other researchers and studies. As several reviews have highlighted 136 (e.g., Gori, Molteni, & Facoetti, 2016), the lack of a validated paradigm and the improper 137 measurement of visual illusion sensitivity (especially amongst individuals with communica-138 tion problems) may be preventing progress in understanding the distinct mechanisms that 139 underlie psychopathology and other fields alike. This is particularly problematic in the con-140 text of the replicability and reproducibility issues recently outlined in psychological science 141 (Maizey & Tzavella, 2019; Milkowski, Hensel, & Hohol, 2018; Nosek, Cohoon, Kidwell, & 142 Spies, 2015; Topalidou, Leblois, Boraud, & Rougier, 2015). Our software, Pyllusion, aims 143 at addressing this gap by proposing and implementing a parametric framework for illusions 144 generation. 145

A Parametric Framework for Illusion Research

146

The core idea of the "parametric" approach proposed here and implemented in *Pyllusion* is to dissociate the parameters of an illusion from its rendered output. For instance, the Ponzo 148 illusion (see Fig. 1) can be described in terms of properties of the "distractor" lines (which induce the illusion), such as the angle (related to the illusion strength), the color, width, 150 etc. and properties of the "target" lines (which are affected in perception by the illusion), 151 such as the size of the smallest line, the objective difference of the ratio of their lengths, or 152 their color, width, etc. This set of parameters can then be rendered in different formats with 153 further format-specific characteristics (in the case of images, the image size, ratio, resolution, 154 compression, etc.). 155

This essentially allows researchers to describe, manipulate, process and share their stimuli in
a concise yet consistent way. For instance, researchers could report a "linear modulation of
the illusion strength between -15 and 15, resulting in a reduced reaction time of...", providing
details about the remaining parameters, as well as the Python code used to fully reproduce
their stimuli.

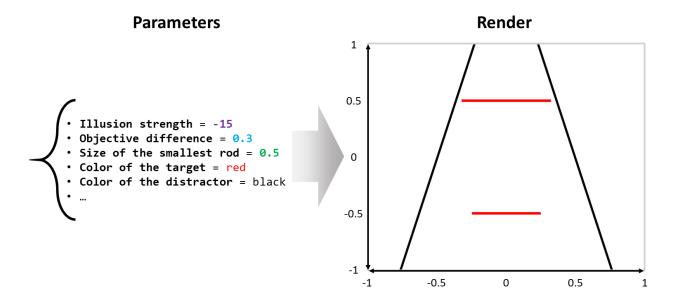

Figure 1. The parametric framework for illusions originally implemented in *Pyllusion* aims at dissociating the *parametric* representation of an illusion (on the left) from its *rendered* representation, in this case as an image of the Ponzo illusion (on the right). In technical terms, an illusion strength of -15 represents a 15 degree tilt of the vertical lines (black distractor lines); an objective difference of 0.3 represents a 30% length difference of the upper and lower horizontal lines (red target lines) where the size of the shorter horizontal line is 0.5.

Moreover, this parametric approach is scalable and works well with different kinds of illusions,
as demonstrated in the software. Indeed, many visual illusions (especially the classical ones)
appear to have relatively similar parameters (such as a feature - like the angle or the size of
some shapes - related to the strength of the illusion, or the color of the "target" objects),
which in turn allows for a consistent application programming interface (API).

Interestingly, in most of the visual illusions, the strength of the illusion can be dissociated from the actual "difference" (which is impacted by the illusion). For instance, in the Müller-Lyer illusion (see **Fig. 1**), the difference between the two horizontal segments can be modulated orthogonally from the angle of the "distractors" arrows. Allowing researchers to easily manipulate these parameters opens the door for potentially interesting paradigms

and experiments. In the following section, we will describe with concrete examples how we operationalized such a parametric approach in the *Pyllusion* software.

173 Pyllusion

This is not the first time that Python, illusions and cognitive science are brought together.

In his book, "Programming visual illusions for everyone", Bertamini (2017) describes how

to use PsychoPy to generate famous illusions. That said, although being a fantastic tool

and resource for researchers and anybody interested in illusions, it is presented as a fun

introduction to programming and to Python, rather than a dedicated software for illusions

per se.

Pyllusion is an open-source package to programmatically generate illusions written in Python 180 3 (Van Rossum & Drake, 2009), which means that its users benefit from a large number of 181 learning resources and a vibrant community. However, although being a programming-182 based tool, users not familiar with Python or other languages can easily use it as well, as it 183 requires minimal programming skills (one can essentially copy the few necessary lines from 184 the documentation and tweak the explicitly-named parameters). This makes it a very flexible 185 tool; advanced users can incorporate Pyllusion in their scripts or experiments (for instance, 186 to generate illusions "on the fly" based on the input of the user), whereas novice users can 187 simply copy the minimal code to pre-generate and save the illusions as images. 188

The source code is available under the MIT license on GitHub (https://github.com/RealityBending/
Pyllusion/). Its documentation (https://realitybending.github.io/Pyllusion/) is automatically built and rendered from the code and includes guides for installation, a description of
the package's functions, as well as examples of use. Finally, the issue tracker on GitHub offers a convenient and public forum that allows users to report bugs, get help and gain insight
into the development of the package. Additionally, the repository leverages a comprehensive
test suite (using pytest) and continuous integration (using GitHub actions) to ensure soft-

ware stability and quality. The test coverage and build status can transparently be tracked 196 via the GitHub repository. Thanks to its collaborative and open development, Pullusion 197 can continuously evolve, adapt, and integrate new functionalities to meet the needs of the 198 community. 199 Pyllusion is available on PyPI, the main repository of software for Python and can thus be 200 installed by running the command pip install pyllusion. Once the software is installed, 201 it must be loaded in Python scripts with import pyllusion. Once the package is loaded, 202 two further steps are required to generate the illusions, 1) specifying the parameters and 2) 203 rendering the output accordingly. We will use the Delboeuf illusion in the hands-on example shown below. However, the same 205 workflow applies to the other illusions supported by Pyllusion, including the Ebbinghaus 206 illusion, the Müller-Lyer illusion, the Ponzo illusion, the Zöllner illusion, the Rod and Frame 207

210 Step 1: Parameters

on the **readme**.

208

209

The parameters for each illusion can be generated using the IllusionName_parameters()
function. Many optional arguments are available for modifying, of which the description
and default values can be found in the API documentation (https://realitybending.github.
io/Pyllusion/functions.html). In the example below, we specify the illusion_strength
argument, and the function will compute all of the remaining parameters accordingly.

illusion, the Poggendorff illusion and more (see Fig. 2, as well as the full list with examples

```
# Load package
import pyllusion as ill

# Create parameters
parameters = ill.(illusion_strength=2)
```

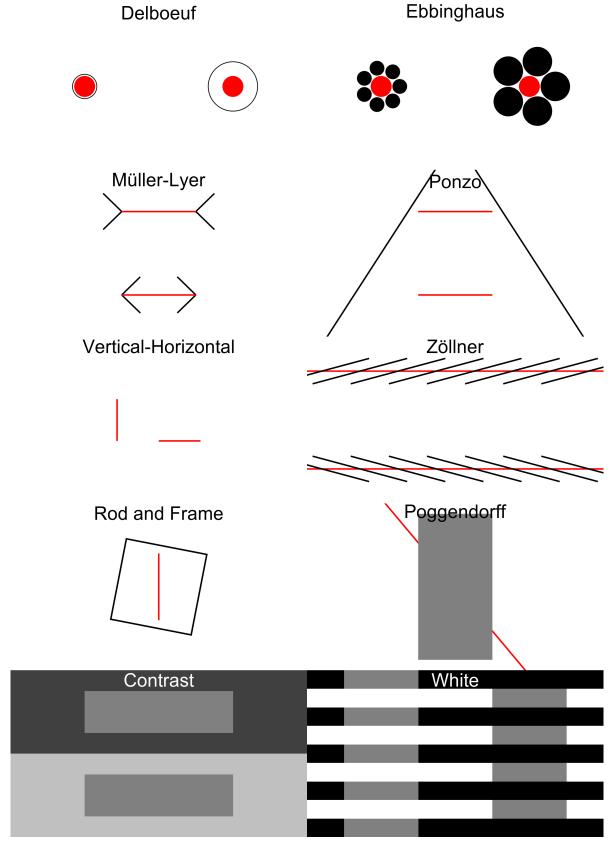

Figure 2. Different classical visual illusions currently supported by *Pyllusion*. These can all be generated using the parametric approach described in this paper, allowing for fully reproducible studies.

```
# Visualize parameters
print(parameters)
```

```
{'Difference': 0,
    'Size_Inner_Left': 0.25,
    'Size_Inner_Right': 0.25,
    'Size_Inner_Difference': 0.0,
    'Illusion_Strength': 2,
    'Size_Outer_Left': 0.3,
    'Size_Outer_Right': 0.52,
    'Distance_Centers': 1,
    'Distance_Edges_Outer': 0.59,
    'Position_Left': -0.5,
    'Position_Right': 0.5,
    ...}
```

As one can see, the output of this function is a basic Python dictionary (as denoted by the 216 curly brackets), which makes it easy to further process, modify, share, store or investigate. 217 This "container" object stores the values for a large number of parameters, such as the size 218 of each (inner and outer) circle, the distance between the centers and edges of the circles, 219 and their position, which is then passed to a "rendering" function which converts this set of 220 parameters into the final output. 221 Note the two main parameters, illusion_strength, and difference, have fairly generic 222 names. For instance, in the Ponzo illusion, less abstract names for these arguments could have been difference size outer circles and difference size inner circles). Indeed, 224 the meaning of these parameters depends on the nature of the illusion. For instance, while 225 illusion_strength currently refers to the the area of the outer circles in the Delboeuf 226

illusion, it refers to the angle of the non-horizontal lines in the Ponzo illusion.

Conceptually, this term represents the extent to which the surrounding context biases the
perceptual experience (see **Fig. 2**). The decision to unify the inducing parameters under
the "illusion strength" label was further motivated by the aim of having a consistent naming
scheme for the API. This means that users can experiment with new illusions by modulating
the illusion strength, without the need of learning what is the actual physical parameter
(e.g., "angle of the distractor lines") driving the illusion.

Step 2: Rendering

The dictionary containing the parameters of the illusion, can then be passed to a "rendering" function, which actually draws (or displays) the illusion according to the specifications.

Render-specific arguments are available at this stage, such as the dimensions of the image.

Two output-engines are currently supported, images [in any format thanks to the PIL Python library for image processing; Clark (2015)], or as *PsychoPy* stimuli (Peirce, 2007), one of the most popular psychological experiments software.

Each function is illusion-specific and hence, uniform function names (in the form IllusionName FunctionGoal()) are used in the process of creating the illusion. Parameters are computed using *_parameters() (the asterisk representing the illusion name), and 243 images can be generated via * image() (or similarly, * psychopy(), as we will see later). The following Python code shows the full and reproducible code to generate a PNG image 245 with a Delboeuf illusion. However, note that the parameters generation and the rendering have been dissociated for illustrative purposes. In practice, the arguments related to the parameters of the illusion can be passed directly to the rendering function, which will automatically compute the parameters if no dictionary is passed. Similarly, the saving step 249 can be done directly by adding .save() at the end of the the *_image() function, which 250 reduces the amount of Python lines to one. 251

```
# Load package
import pyllusion as ill
# Create parameters
parameters = ill.delboeuf parameters(illusion strength=1, difference=2)
# Generate image from parameters
image = ill.delboeuf image(parameters, height=600, width=800)
# Save it
image.save("my illusion.png")
Images can be easily post-processed using the PIL library. For instance, with just a few lines,
```

one can loop through different combinations of parameters, generate illusions, add text on them, and collate together in a mosaic, as can be seen in Fig. 3. **PsychoPy.** As illusions are frequently used in experimental psychology, we designed Pyl-255 lusion so that it is directly usable within PsychoPy (Peirce, 2007) experiments. PsychoPy is 256 an open-source, free and Python-based package for experiment creation, recognized for its 257 timing accuracy (Bridges, Pitiot, MacAskill, & Peirce, 2020) and its GUI (the "builder"), 258 thereby allowing users who are not familiar with code to easily build experiments. 259 The PsychoPy "builder" interface allows for code components to be flexibly added, which 260 makes it convenient to insert the few lines necessary for displaying illusions. However, using the programming interface of PsychoPy (which underlies the graphical interface) reveals how seamless the integration with *Pyllusion* can be. The following code is a minimal example 263 demonstrating how to use a Delboeuf illusion within a PsychoPy workflow. Running it opens 264 a new window, displays the illusion in it, and then closes it once an input (a key press) is 265 detected.

252

266

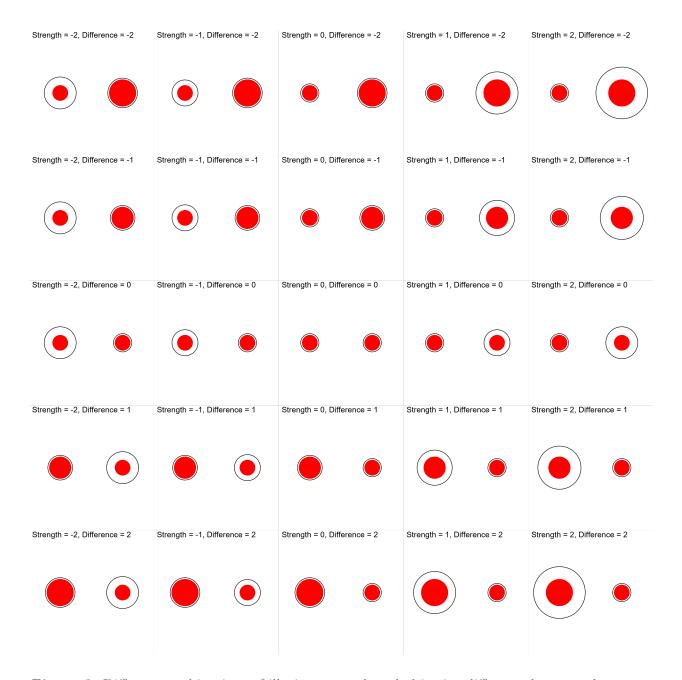

Figure 3. Different combinations of illusion strength and objective difference between the two target stimuli (the area of the red circles) for the Delboeuf illusion. The vertical central column shows varying magnitudes of size difference in both directions with no illusion, whereas the horizontal central row shows different magnitudes of illusion strength when the targets are of identical sizes. By using negative or positive values for the illusion strength, one can generate congruent or incongruent illusions (that reinforce or attenuate the actual difference respectively).

```
# Load packages
import pyllusion as ill
from psychopy import visual, event
# Create parameters
parameters = ill.delboeuf parameters(illusion strength=1, difference=2)
# Initiate Window
window = visual.Window(size=[800, 600], winType='pygame', color='white')
# Display illusion
ill.delboeuf psychopy(window=window, parameters=parameters)
# Refresh and close window
window.flip()
event.waitKeys() # Press any key to close
window.close()
```

This native integration with *PsychoPy* could appear as somewhat redundant and unnecessary, as one could pre-generate all the illusions as images, and simply load them in *PsychoPy* as images, instead of generating them from scratch using *PsychoPy*'s drawing functionalities.

However, this direct integration in experiment building software has multiple benefits, such as avoiding the storage of large image file sizes (resulting in more efficient use of space for experiments that can be uploaded and stored online), avoiding issues of image scaling and resolution on different screens, and allowing "on-the-fly" generation of stimuli, which opens the door for novel adaptive paradigms where the modulation of illusions crucially depends on the participant's input.

Future Plans and Developments

276

Being an open-source software, *Pyllusion* will continue to grow and evolve based on the community's input and needs. While the direction and state of the package in the long term can be hard to predict, several short term goals are highlighted below.

The initial release of *Pyllusion* focuses on a set of classical, well-described, visual illusions, as they are the most commonly used (for historical reasons mainly, as well as for their relative simplicity). That said, the number of existing illusions, or variations therein, is virtually infinite [and great advances are made to generate new ones using machine learning; Watanabe, Kitaoka, Sakamoto, Yasugi, and Tanaka (2018)]. Thus, new illusions, as well as new illusion types (e.g., movement-based using GIF or video formats, or auditory illusions using sounds and music) could be added in the future. Due to the open and collaborative nature of the software, these evolutions will be driven by the needs of the community, ensuring that *Pyllusion* remains cutting-edge, adaptable and useful to address future issues.

Adding new illusions refers mostly to implementing an algorithm to conceptualise and essentialize them as sets of parameters, which is by design independent from their rendering.

However, more rendering engines could be added down the road. For instance, one of the first milestones could take the form of an integration with other Python-based experiment building software, such as *OpenSesame* (Mathot, Schreij, & Theeuwes, 2012) or *Neuropsydia* (Makowski & Dutriaux, 2017). Additionally, a conversion to other languages could also be an interesting feature, especially *JavaScript*, as this would allow a closer integration with web browser apps [and online experiments software, such as *jsPsych*; Leeuw and Motz (2016); or *lab.js*; Henninger, Shevchenko, Mertens, Kieslich, and Hilbig (2020)].

Finally, we look forward to the creation of studies that would investigate how, for each illusion, the modulation of the parameters affect behavioural responses, conscious perception, and the associated neural underpinnings. This would in turn allow for a better understanding of the commonalities and differences between these fascinating stimuli, as well as their effect

accross different populations (such as patients suffering from neuropsychiatric disorders). As such, we hope that our tool contributes to the development of a strong axis that will unite the community working with illusions to push the field forward.

Conflict of Interest Statement

The authors declare that the research was conducted in the absence of any commercial or financial relationships that could be construed as a potential conflict of interest.

Acknowledgements

We would like to thank Prof. Mahamaya for her insights regarding illusions.
